On the contrary, in the case of non-linear loads, the current is not proportional to the voltage and it fluctuates according to an alternating load impedance. Non-linear loads can be motor controllers, inverters, welding equipment, MRI scanner, rectifiers, UPS systems, computers, printers, TVs, etc.

Unfortunately, non-linear loads draw in currents in abrupt short pulses. These pulses distort the current waveforms, which in turn generates harmonics, that can lead to power problems. Power problems can affect both the distribution system equipment and the loads connected to it.

Common load models used for non-linear loads include the current source model, harmonic current injection model, and time-domain simulation models. Non-linear loads introduce harmonics into the electrical system, which can cause voltage distortion and affect the performance of other connected equipment.

Model overview. The single-line diagram shown in Figure 1 represents designed distribution system. The electric utility distributes power at 110 kV, which in turn feeds a 20.5 kV distribution system via a 20 kV, 3-phase, 50-Hz, 10MVA distribution transformer.. Further mostly 2000 kVA service transformers are used to step the voltage down from 20.5 kV to 0.4 V.

This white paper defines linear and non-linear loads, describes what characteristics cause a load to be linear or nonlinear, and shows how these load types can affect the distribution system and power quality. On the other hand, with a non-linear load the current isn't proportional to the voltage and it fluctuates based on the alternating load impedance. Common examples of non-linear loads include rectifiers, variable-speed drives and electronic devices such as computers, printers, TVs, servers and telecoms systems that use SMPS power conversion ...

When modeling the distribution system, we can think of each SMPS as a generator of harmonic currents. Each harmonic current injected into the power system by a non-linear load will flow through the system impedance, resulting in a voltage drop at that harmonic frequency. The amount of voltage drop follows Ohm's Law ( $V_h = I_h \times Z_h$ ) where:

A load is considered non-linear if its impedance changes with the applied voltage. The changing impedance means that the current drawn by the non-linear load will not be sinusoidal even when it is connected to a sinusoidal voltage. These non-sinusoidal currents contain harmonic currents that interact with the impedance of the power distribution system to create voltage distortion ...

Capacitive electrical loads can be considered as the dual of inductive loads, where the voltage peaks after the current sine-wave. In a typical household, it is usually assumed that there is no significant capacitive load. Non-linear loads are the ones that the drawn current does not follow a sinusoidal pattern.

A load is considered "non-linear" if its impedance changes with the applied voltage. Due to this changing impedance, the current drawn by the non-linear load is also non-linear i.e. non-sinusoidal in nature, even when it is connected to a sinusoidal voltage source (for example computers, variable frequency drives, discharge lighting etc).
