The fundamentals of photovoltaics are reviewed. The necessary requirements for material properties are discussed. Achieving high efficiency with organic solar cells is known to be difficult for two main reasons. Photon absorption does not directly lead to free charge carriers but to excitons with large binding energies which are difficult to dissociate.

Thus, there is, in principle, no reason why organic solar cells with their inherent advantages, discussed below, should not usher in the third generation of solar cells [6, 7]. At the outset it is necessary to distinguish between the types of organic and polymer materials for PV applications.

In addition, ordered heterojunction solar cells (Fig. 1d) were also developed, and they are considered as an ideal configuration for solar cell application, because they have direct charge transport pathway organic acceptor semiconductors can be made as nanotube, nanorod, and nanowire shaped structures, and they can be vertically aligned onto conducting substrates.
