

Materials for thermo-chemical storage (TCS) are also expensive as they have to be prepared (e.g. pelletised or layered over supporting structures). Also expensive are the containers and the auxiliary TCS equipment for both heat and mass transfer during energy charging and discharging.

Thermal energy (i.e. heat and cold) can be stored as sensible heat in heat storage media, as latent heat associated with phase change materials (PCMs) or as thermo-chemical energy associated with chemical reactions (i.e. thermo-chemical storage) at operation temperatures ranging from -40°C to above 400°C .

Thermal energy storage in the form of sensible heat is based on the specific heat of a storage medium, which is usually kept in storage tanks with high thermal insulation. The most popular and commercial heat storage medium is water, which has a number of residential and industrial applications.

However, in general sensible heat storage requires large volumes because of its low energy density (i.e. three and five times lower than that of PCM and TCS systems, respectively). Furthermore, sensible heat storage systems require proper design to discharge thermal energy at constant temperatures.

Thermal Energy Storage Applications. Thermal energy is a good source of energy. Let's look at some of the good uses of thermal energy. We use thermal energy in solar power plants to provide energy during the night time. Thermal energy is used in cooking, baking, water heating, and heating. It is also used in thermal processing of non-metals.

Although the large latent heat of pure PCMs enables the storage of thermal energy, the cooling capacity and storage efficiency are limited by the relatively low thermal conductivity ($\sim 1 \text{ W}/(\text{m} \cdot \text{K})$) when compared to metals ($\sim 100 \text{ W}/(\text{m} \cdot \text{K})$). 8, 9 To achieve both high energy density and cooling capacity, PCMs having both high latent heat and high thermal ...

Thermal energy storage means heating or cooling a medium to use the energy when needed later. Sensible heat storage is achieved by increasing (heating) or decreasing (cooling) the temperature of the storage medium. A typical cycle of sensible heat thermal energy storage (SHTES) system involves sensible heating and cooling processes as given in Fig. 3.3. The heating (or cooling) process increases (or reduces) the enthalpy of the storage medium.

In most cases, storage is based on a solid/liquid phase change with energy densities on the order of 100 kWh/m³ (e.g. ice). Thermo-chemical storage (TCS) systems can reach storage capacities of up to 250 kWh/t with operation temperatures of more than 300°C and efficiencies from 75% to nearly 100%.
